is a serious complication can then lead to a potentially fatal blood infection called sepsis. What Are the Risk Factors for Appendicitis? There's no way to predict who will get appendicitis, but scientists have uncovered several risk factors for the condition. (9) Measles, a highly contagious virus spread through the air and contact. Often, appendicitis is probably the result of an obstruction of the area inside the appendix called the appendiceal lumen (the interior of the tube of the appendix), or appendix lumen. Long considered to be a vestigial organ without much purpose, the appendix, some experts now think, is involved in both encouraging and protecting the growth of beneficial gut bacteria: When certain diseases destroy beneficial gut bacteria in the GI tract, the appendix helps to recolonize the gut after infection. In fact, recent research has focused on the role the appendix might play in immune function. (15) There's also a link between air pollution – in particular, high levels of ozone – and appendicitis. Appendicitis is a serious medical condition in which the appendix – a small, finger-shaped organ attached to your large intestine – becomes swollen and inflamed. Most strains of E. (8) Salmonella, a foodborne bacteria that typically causes gastrointestinal upset (diarrhea, nausea, and vomiting) but can have serious complications. Shigella bacteria, germs that are very similar to E. coli, cause shigellosis, a disease that causes bloody diarrhea and inflammation of the large intestine. (10) Intestinal worms or parasites, including pinworm (Enterobius vermicularis). Irritation and ulcers in the gastrointestinal (GI) tract resulting from long-lasting disorders, such as Crohn's disease or ulcerative colitis. Abdominal injury or trauma. Enlarged lymph tissue of the wall of the appendix, which is typically the result of infections in the GI tract. Benign or malignant tumors. Various foreign objects, such as stones, bullets, air gun pellets, and pins. (3) Sometimes appendicitis is due to a viral, bacterial, or fungal infection that has spread to the appendix. (12) But when the organ becomes infected or obstructed, bacteria in the appendix multiply rapidly, causing your appendix to swell and fill with pus – a thick liquid containing bacteria, tissue cells, inflammatory debris, and dead infection-fighting white blood cells. The Possible Complications of Appendicitis If left untreated, appendicitis will often get progressively worse as the inflammation leads to further complications. More on Complications of Appendicitis Pressure within the appendix will increase, limiting the amount of blood flowing through the walls of the appendix, where the tissue then becomes starved of blood and starts to die. Eventually, the appendix will rupture, leaking its contents throughout the abdomen. Vaccination protects most of the population, but there are outbreaks in which unvaccinated people are susceptible. (16) The fungal infection mucormycosis (a rare but serious mold infection caused by environmental molds) (11) and histoplasmosis; most people who breathe in these spores won't get sick or will have mild symptoms, but infection can become severe in people with weakened immune systems. (11) Your appendix is home to many beneficial bacteria. (17) (16) Studies suggest that people get appendicitis more during the summer than at other times of the year. These include: Being a teenager or in your twenties; (13) most cases of appendicitis occur in this age group. Having a long-lasting inflammatory bowel disease, such as Crohn's disease or ulcerative colitis. Studies have suggested that family history plays a role. (10) A study published in 2010 in the Western Journal of Emergency Medicine found that among adults at an emergency room who were treated with appendicitis, those with a known family history were more likely to have the condition. (14) And a study published in 2008 in the Journal of Pediatric Surgery found that "heredity is a significant risk factor for childhood appendicitis." (10) Appendicitis is also linked to increased exposure to air pollution, but the link is not clear. (18) A review of over 40 years of research, published in February 2014 in Annals of Medical and Health Sciences Research, concludes that it's likely due to a combination of increased exposure to air pollution and more GI infections during summer months. In some cases, abscesses (pockets of pus) may form on the ruptured appendix if the abscesses tear, they can infect the rest of the abdomen. In other cases, the ruptured appendix may cause the peritoneum – the silk-like membrane that lines the abdominal cavity – to become infected, a condition called peritonitis. (3) Pseudomonas bacteria, which are found in soil and water and moist areas such as sinks and toilets. (6) Bacteroides, bacteria that already inhabit the digestive tract of humans. (7) Adenovirus, a very common virus spread through contact or through the air that can cause cold-like symptoms as well as bladder and other infections. It's not always clear what causes appendicitis, coli, which are bacteria found in the environment, foods, and intestines of animals.
